### ABSTRACT

The formulation of a soil structure interaction problem begins with identifying the underlying design variables which are primarily varied during the analysis process. In design, construction and maintenance of any Engineering system, Engineers have to take many technological and managerial decisions at several stages. Structural deflections are the process of finding the conditions that give the maximum or minimum value of a function. A design problem usually involves many design parameters of which some are highly sensitive to the proper working of the design. The nonlinear soil structure reactions along the circumference and on the base of the beam are modeled realistically by using suitable translational and rotational nonlinear interaction springs. Dynamic Analysis is used to find stress-strain in a soil structure interaction once the loading on the structure is known. Resulting load path change in the system could become a major source of discrepancy between the measured load and the load in the actual system. The proposed measurement technique by using the whole soil structure interaction component altered, as its own load cell. The dynamic engineering properties for soil and structure are considered as variable for analysis. The soil and structural response model are developed in the behavior of dynamic loading.

**Keywords:** Soil Properties, shear wave velocity, Shallow foundation.

### Dynamic Soil Properties

To measure the dynamic properties for the emergency situation the dynamic analysis of shallow foundation for various structures can be analyzed. Shear wave velocity and cyclic plate load test can be used to measure the dynamic analysis.

### Soil Mass

The soil mass below the foundation is layer by layer size for the continuity and compatibility in stress –strain for X, Y, Z direction. The soil mass is assumed to be nonlinear for the study. Bearing capacity, properties of soil and properties of hard rock are discussed in Table1,2 and 3.

**Table – 1 Bearing Capacity**

| Bore Hole No | Sample Depth (m) | Unit Weight (kN/m <sup>3</sup> ) | Angle of Friction $\phi^\circ$ | Cohesion C (kN/m <sup>3</sup> ) | Allowable Bearing capacity (kN/m <sup>2</sup> ) |
|--------------|------------------|----------------------------------|--------------------------------|---------------------------------|---|
| 1            | 5                | 18.95                            | 6                              | 41                              | 125   |
|              | 10               | 18.95                            | 6                              | 41                              | 137   |
|              | 15               | 18.95                            | 6                              | 41                              | 141   |
|              | 20               | 18.95                            | 6                              | 41                              | 146   |

**Table – 3 Properties of Hard Rock**

| Bore Hole No. | Depth (m) | Specific Gravity | Water Absorption (%) | Compressive strength (kg/cm <sup>2</sup> ) |
|---------------|-----------|------------------|----------------------|--|
| 1             | 45        | 2.233            | 10.75                | 107  |
| 2             | 45        | 2.455            | 10.45                | 102  |

The effective of shear wave velocity is considerate for foundation dimensions, overburden pressures from the structure, nonlinear effects and the calculation of the foundation stiffness and damping.

### Structure on shallow foundation

Shallow foundation of 350x350x450m has been modeled using thick R.C. C, to simulate the Soil Structure Interaction effects for the layered soil. The properties of soil have adopted and calculated, are shown in Table-4. The spring stiffness values for vertical, horizontal, rocking and twisting motions are calculated as per Richart and Lysmer model. The whole area is covered with linear and nonlinear springs are applied.

**Table- 4 Spring stiffness for various types of soil**

| Stiffness of soil spring (kN/m)          |           |             |            |           |
|--|-----------|-------------|------------|-----------|
| Soil Type                                | Hard      | Dense       | Stiff      | Soft      |
| Horizontal <i>Longitudinal Direction</i> | 79395673  | 16348716    | 4135675    | 3125109   |
| Horizontal <i>Lateral Direction</i>      | 81393210  | 1834190152  | 4287140    | 3012853   |
| Vertical                                 | 96017651  | 21783590141 | 378301726  | 4591035   |
| Rocking(about Longitudinal Direction)    | 129836710 | 3891026704  | 172427181  | 123841810 |
| Rocking(about Lateral Direction)         | 193825701 | 3450284502  | 490138104  | 114561801 |
| Torsion                                  | 71303891  | 649132102   | 1023481902 | 30158315  |

## Description of soil and foundation

Field response analysis of soil profile is Hard, Dense, stiff, soft was considered. The properties of this soil are given in Table- 5.

**Table – 5 Properties of Hard, Dense, Stiff & Soft**

| Type of Soil (Description) | Shear Velocity Vs (m/sec) | Shear Modulus (kN/m <sup>2</sup> ) | Elastic Modulus 'E' (kN/m <sup>2</sup> ) | Poisson's ratio (μ) |
|----------------------------|---------------------------|------------------------------------|--|---------------------|
| Soil 1(Hard)               | 850                       | 71863.56                           | 121.2x 10 <sup>4</sup>                   | 0.5                 |
| Soil 2(Dense)              | 575                       | 56342.5                            | 73.5 x 10 <sup>4</sup>                   | 0.4                 |
| Soil 3(Stiff)              | 435                       | 47831.7                            | 51.7 x 10 <sup>4</sup>                   | 0.39                |
| Soil 4(Soft)               | 320                       | 10345.7                            | 26.7 x 10 <sup>4</sup>                   | 0.35                |

## In situ and laboratory test results

In situ tests was carried out, including pressure meter tests, down-hole seismic, and cross-hole seismic and cross-hole tomography to determine compression and shear wave velocities through the ground profile. The vertical wave velocity with depth gave a useful indication of variations in the nature of the strata between the borelogs. Basic laboratory classification tests (moisture content of soil and rock, Atterberg limits, particle size distribution and hydrometer) and laboratory tests for determining physical properties (porosity tests, intact dry density, specific gravity, particle density) and chemical properties were carried out. In addition, unconfined compression tests, consolidation test, point load index tests, and drained direct shear.

## Field investigation and site characterization

The investigations involved the drilling of 2 boreholes to a maximum depth of about 30 m below ground level. Standpipe piezometers were installed to measure the ground water level which was found to be relatively close to the ground surface, typically at a level of 2.5m DMD. The ranges of measured SPT N values are summarised in Table 1. There was a tendency for N values to increase with depth, beyond an elevation of about -51m DMD.

Table 1: Measured SPT Values

| Elevation m | Range of SPT Values |
|-------------|---------------------|
| 0 to -1     | 0-32                |
| -1 to -7    | 40-300              |
| -7 to -15   | 30-150              |
| -15 to -25  | 50-270              |
| -25 to -35  | 130-250             |

## Winkler Model

The soil medium as linear or non-linear elastic springs and it is a idealized soil medium. It is adequate suitable for computational purpose. This type of model is used to study the geotechnical analysis for the soil behavior and structural response of the modeling. it can be specify the boundary condition

## Geotechnical and structural Model

Force-deformation behaviour is assigned to the spring representing the lateral stiffness of the system .The parameters for the assessment of the settlement characteristics of the soil foundation system are the values of the Young's modulus of the strata for structural behaviour under dynamic loading. In a non-linear analysis, the values of ultimate bearing capacity of the foundation would be required, in this paper; non linear elastic analyses have been undertaken using dynamic analyses. It's experienced the non linearity up to the maximum load level. Attention has thus been focussed on evaluating relevant values of Young's modulus for each stratum. As a first, the relative stiffness of the various soil layers values has been assessed by considering values of the Young's Modulus from the following data:

1. Pressuremeter tests (first loading, second loading, first reload, second reload cycles);
2. Resonant column tests (Initial, 0.0001%, 0.001%, 0.01% strain levels),

3. Triaxial Stress Path Tests (0.01% and 0.2% strain levels),
4. Geophysics tests

### Calculating Displacements of Joints

To display the failure mechanism the spring model has been developed for calculating the displacements of the joints of the failure mechanism. The displacements of footing column joint are obtained relative to the support. The members connected to the joint and identified whether it's a plastic hinge exist at the end of these members. If the known set of plastic hinge rotations at the base, the displacements of the joint under consideration are found by successive translation and rotation about that joint. The stress- strain results are obtained from the one-dimensional beam model.

### Specification of foundation model for consideration of base SSI

| Elements of Structures | Dimensions (mm) |
|------------------------|-----------------|
| Column c/s             | 450 x 450       |
| Footing (Lx B x Tk.)   | 350 x 350 x 150 |
| Column Height          | 400             |

### Structural properties

| Concrete Material     |                          |
|-----------------------|--------------------------|
| Young's Modulus $E_c$ | 20650 Nmm <sup>2</sup>   |
| Density               | 2250 kg/m <sup>3</sup>   |
| Poisson's Ratio       | 0.17                     |
| Compressive Strength  | 20 N/mm <sup>2</sup>     |
| Reinforcing Steel     |                          |
| Young's Modulus $E_s$ | 200000 N/mm <sup>2</sup> |
| Yield Strength $f_y$  | 450 N/mm <sup>2</sup>    |

Structural nonlinearity is considering foundation response will satisfy the structural response and soil structure interaction effects. Non-linear force displacement of the structure gives a more effects to the soil.

### Shear wave velocity

The initial shear wave velocity increases, the variation in the response modification factors reduces, such that the response modification factors approaches to 1.1. It known as increase in initial shear wave velocity with respect to the stiff foundation condition. Soil-structure systems are forced to a more to that of the corresponding base systems. Due to large reduction in total displacement and structural drift may occur and for a very small amplification is expected for structural acceleration and structural distortion.

### Displacements

Table 6 shows the various reading on the depth and displacement the Figure- 1 represents displacement and the depth graph. Displacement along X axis (denoted in mm) and depth along Y axis (denoted in mm) it also denotes that when depth increases displacement also increases. This displacement depends on loadings in the layered soil.

**Table 6 Displacement vs Depth**

| Displacement (mm) | Depth (mm) |
|-------------------|------------|
| -                 | 0          |
| 15                | 200        |
| 30                | 400        |
| 67                | 600        |
| 87                | 800        |

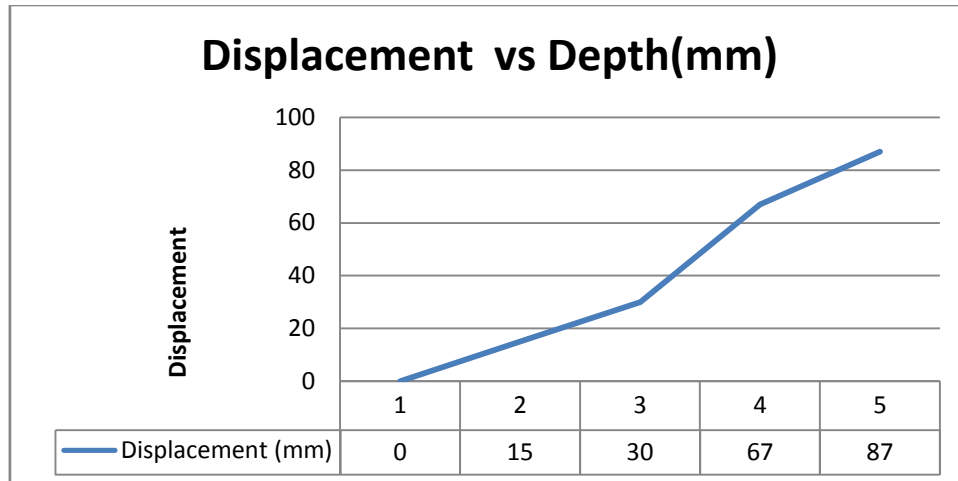

Figure-1 Displacement vs Depth

### Base Shear

The lateral force occur at the base of the structure due to an earthquake is called as base shear. The base shear of the structure can be affected by the ground motions with respect to different layered soil conditions. Base shear results of the shallow foundation with fixed base and flexible base are shown in Table – 7. For the base shear the soil model will decrease the range from 5 % to 8% in comparison with the fixed base, the spring model range is 11 % to 16%.

Table – 7 Base shear for Flexible and Fixed Base

| Soil Type     |       | Base Shear kN |
|---------------|-------|---------------|
| Flexible Base | Hard  | 509.51        |
|               | Dense | 631.84        |
|               | Stiff | 719.45        |
|               | Soft  | 861.45        |
| Fixed Base    | Hard  | 732.89        |
|               | Dense | 792.85        |
|               | Stiff | 861.45        |
|               | Soft  | 964.93        |

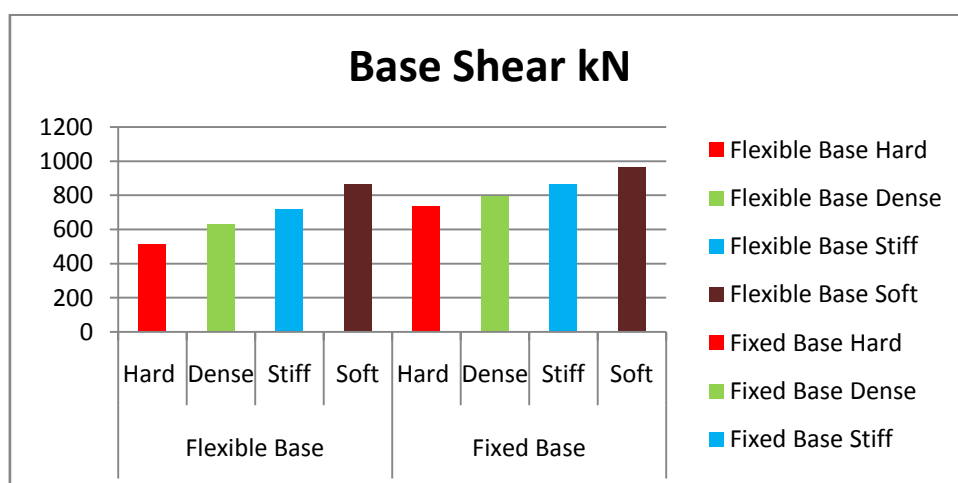

Fig.1 Base shear comparison of shallow foundation for Flexible and Fixed base condition.

### Conclusion

The structure was modeled by soil foundation using springs; the effect of the soil structure interaction was considered the displacement and acceleration of the building. The nonlinear governing equations have been achieved. The displacement of winker foundation is more sensitive for non-linear analysis. Nonlinear model can be misleading in the prediction of foundation deformation.
